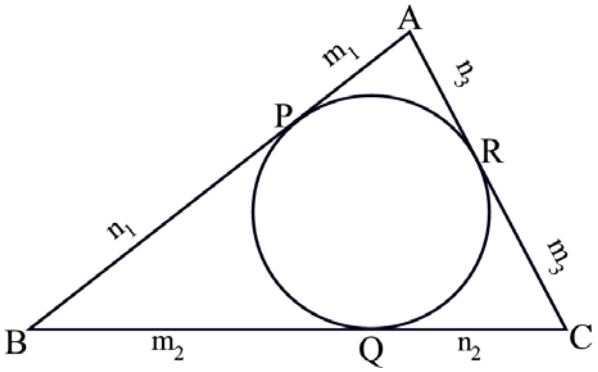
Problem E

In-Circle

Input: Standard Input
Output: Standard Output

In-circle of a triangle is the circle that touches all the three sides of the triangle internally. The center of the in-circle of a triangle happens to be the common intersection point of the three bisectors of the internal angles. In this problem you will not be asked to find the in-circle of a triangle, but will be asked to do the opposite!!



You can see in the figure above that the in-circle of triangle ABC touches the sides AB, BC and CA at point P, Q and R respectively and P, Q and R divides AB, BC and CA in ratio m1:n1, m2:n2 and m3:n3 respectively. Given these ratios and the value of the radius of in-circle, you have to find the area of triangle ABC.

Input

First line of the input file contains an integer N (0<N<50001), which denotes how many input sets are to follow. The description of each set is given below.

Each set consists of four lines. The first line contains a floating-point number r (1<r<5000), which denotes the radius of the in-circle. Each of the next three lines contains two floating-point numbers, which denote the values of m_1, n_1, m_2, n_2, m_3 and n_3 ($1<m_1, n_1, m_2, n_2, m_3, n_3<50000$) respectively.

Output

For each set of input produce one line of output. This line contains a floating-point number that denotes the area of the triangle ABC. This floating-point number should contain four digits after the decimal point. Errors less than $5*10^{-3}$ will be ignored. Use double-precision floating-point number for calculation.
