## Problem J

## Bits

Input: Standard Input
Output: Standard Output
A bit is a binary digit, taking a logical value of either "1" or " 0 " (also referred to as "true" or "false" respectively). And every decimal number has a binary representation which is actually a series of bits. If a bit of a number is " 1 " and it's next bit is also " 1 " then we can say that the number has a 1 adjacent bit. And you have to find out how many times this scenario occurs for all numbers up to $\mathbf{N}$.

Examples:

| Number | Binary | Adjacent Bits |
| :--- | :--- | :---: |
| 12 | 1100 | 1 |
| 15 | 1111 | 3 |
| 27 | 11011 | 2 |

## Input

For each test case, you are given an integer number ( $0<=\mathrm{N}<=\left(\left(2^{\wedge} 63\right)-2\right)$ ), as described in the statement. The last test case is followed by a negative integer in a line by itself, denoting the end of input file.

## Output

For every test case, print a line of the form "Case X: Y", where X is the serial of output (starting from 1 ) and $Y$ is the cumulative summation of all adjacent bits from 0 to N .

## Sample Input

| 0 |  |
| :--- | :--- |
| 6 |  |
| 15 |  |
| 20 |  |
| 21 |  |
| 22 |  |
| -1 |  |

Output for Sample Input
Case 1: 0
Case 2: 2
Case $3: 12$
Case 4: 13
Case 5: 13
Case 6: 14
