Some people think that the bigger an elephant is, the smarter it is. To disprove this, you want to take the data on a collection of elephants and put as large a subset of this data as possible into a sequence so that the weights are increasing, but the IQ's are decreasing.

## Input

The input will consist of data for a bunch of elephants, one elephant per line, terminated by the end-of-file. The data for a particular elephant will consist of a pair of integers: the first representing its size in kilograms and the second representing its IQ in hundredths of IQ points. Both integers are between 1 and 10000 . The data will contain information for at most 1000 elephants. Two elephants may have the same weight, the same IQ, or even the same weight and IQ.

## Output

Say that the numbers on the i-th data line are $W[i]$ and $S[i]$. Your program should output a sequence of lines of data; the first line should contain a number $n$; the remaining $n$ lines should each contain a single positive integer (each one representing an elephant). If these $n$ integers are $a[1], a[2], \ldots, a[n]$ then it must be the case that

$$
W[a[1]]<W[a[2]]<\ldots<W[a[n]]
$$

and

$$
S[a[1]]>S[a[2]]>\ldots>S[a[n]]
$$

In order for the answer to be correct, $n$ should be as large as possible. All inequalities are strict: weights must be strictly increasing, and IQs must be strictly decreasing.

There may be many correct outputs for a given input, your program only needs to find one.

## Sample Input

60081300
60002100
5002000
10004000
11003000
60002000
80001400
60001200
20001900

## Sample Output

4
