

You can see in the pictures below that two different circles can have at most four common tangents. Given the center and radius of two circles your job is to find the length of their common tangents and also the points where they touch the two circles.

## Input

The input file contains several lines of inputs.

Each line contains six integers  $x_1$  ( $-100 \leq x_1 \leq 100$ ),  $y_1$  ( $-100 \leq y_1 \leq 100$ ),  $r_1$  ( $0 < r_1 \leq 200$ ),  $x_2$  ( $-100 \leq x_2 \leq 100$ ),  $y_2$  ( $-100 \leq y_2 \leq 100$ ),  $r_2$  ( $0 < r_2 \leq 200$ ). Here  $(x_1, y_1)$  and  $(x_2, y_2)$  are the coordinates of the center of the first circle and second circle respectively,  $r_1$  is the radius of the first circle and  $r_2$  is the radius of the second circle.

Input is terminated by a line containing six zeroes.

## Output

For each line of input you should produce one or more lines of output. The description of this output is given below.

First line of the output for each line of input contains an integer  $n$ , which denotes the number of different tangents between the two circles. If there is infinite number of tangents between the two circles then the value of  $n$  should be '-1'. If  $n$  is positive then next  $n$  lines contains the description of each tangent. The description of the tangent contains five floating-point numbers  $S_x$ ,  $S_y$ ,  $T_x$ ,  $T_y$ ,  $L$  in a single line. Here  $(S_x, S_y)$  is the point at which the tangent touches the first circle and  $(T_x, T_y)$  is the point where the tangent touches the second circle and  $L$  is the length of the tangent. All the floating-point numbers have five digits after the decimal point. Errors less than  $2 * 10^{-5}$  will be ignored. The tangents should be printed in ascending order of  $S_x$  and in case of a tie they should be printed in ascending order of  $S_y$ .

## Sample Input

```
10 10 5 20 20 5
10 10 10 20 20 10
10 10 5 20 10 5
0 0 0 0 0 0
```

## Sample Output
