

A positive integer may be expressed as a sum of different prime numbers (primes), in one way or another. Given two positive integers  $n$  and  $k$ , you should count the number of ways to express  $n$  as a sum of  $k$  different primes. Here, two ways are considered to be the same if they sum up the same set of the primes. For example, 8 can be expressed as  $3 + 5$  and  $5 + 3$  but they are not distinguished.

When  $n$  and  $k$  are 24 and 3 respectively, the answer is two because there are two sets  $\{2, 3, 19\}$  and  $\{2, 5, 17\}$  whose sums are equal to 24. There are no other sets of three primes that sum up to 24. For  $n = 24$  and  $k = 2$ , the answer is three, because there are three sets  $\{5, 19\}$ ,  $\{7, 17\}$  and  $\{11, 13\}$ . For  $n = 2$  and  $k = 1$ , the answer is one, because there is only one set  $\{2\}$  whose sum is 2. For  $n = 1$  and  $k = 1$ , the answer is zero. As 1 is not a prime, you shouldn't count  $\{1\}$ . For  $n = 4$  and  $k = 2$ , the answer is zero, because there are no sets of two different primes whose sums are 4.

Your job is to write a program that reports the number of such ways for the given  $n$  and  $k$ .

## Input

The input is a sequence of datasets followed by a line containing two zeros separated by a space. A dataset is a line containing two positive integers  $n$  and  $k$  separated by a space. You may assume that  $n \leq 1120$  and  $k \leq 14$ .

## Output

The output should be composed of lines, each corresponding to an input dataset. An output line should contain one non-negative integer indicating the number of ways for  $n$  and  $k$  specified in the corresponding dataset. You may assume that it is less than  $2^{31}$ .

## Sample Input

```
24 3
24 2
2 1
1 1
4 2
18 3
17 1
17 3
17 4
100 5
1000 10
1120 14
0 0
```

## Sample Output
