

## 13050 Discovering Paths

Given a grid with  $R$  rows and  $C$  columns, you are currently at  $(0, 0)$  and you want to go to the position  $(R - 1, C - 1)$ . You have only two kind of movement allowed. From any position  $(i, j)$  you can go to either  $(i + 1, j)$  or  $(i, j + 1)$ . You need to find the number of ways you can go to  $(R - 1, C - 1)$  from  $(0, 0)$ . Easy, right? But here's is a slight problem. All the cells are not available all the time. So while counting the number of ways you need to consider that you can never step into a cell which is not available right now.

### Input

First line will contain an integer  $T$  ( $1 \leq T \leq 10$ ), which is the number of test cases. Each case starts with a line  $R, C$  and  $Q$ . Here,  $1 \leq R, C \leq 1000$  and  $1 \leq Q \leq 10000$ . Then,  $Q$  queries follow, each with four integers  $a, b, c, d$ . This means the cells inside the rectangle with lower left corner at  $(a, b)$  and upper right corner at  $(c, d)$  are not available. All the coordinates are given in row major order with 0-based indexing. The lowermost and leftmost point is considered to be  $(0, 0)$ .

### Output

For each case print a line 'Case  $T$ ', where  $T$  is the case number. For each query in a case, print 3 spaces and then 'Query  $X$ :  $W$ ', where  $X$  is query number and  $W$  is the number of ways possible for that particular query. Answer needs to be in *modulo* 912. Check sample input and output for details.

### Sample Input

```
1
5 5 2
1 1 2 2
0 1 2 3
```

### Sample Output

```
Case 1
  Query 1: 10
  Query 2: 5
```
