At a certain laboratory results of *secret research* are thoroughly encrypted. A result of a single experiment is stored as an information of its completion:

'positive result', 'negative result', 'experiment failed' or 'experiment not completed'

The encrypted result constitutes a string of digits S, which may take one of the following forms:

- positive result
  negative result
  experiment failed S = 1 or S = 4 or S = 78 S = S35 S = 9S4
- experiment not completed S = 190S

(A sample result S35 means that if we add digits 35 from the right hand side to a digit sequence then we shall get the digit sequence corresponding to a failed experiment)

You are to write a program which decrypts given sequences of digits.

## Input

A integer n stating the number of encrypted results and then consecutive n lines, each containing a sequence of digits given as ASCII strings.

## Output

For each analysed sequence of digits the following lines should be sent to output (in separate lines):

- + for a positive result
- for a negative result
- \* for a failed experiment
- ? for a not completed experiment

In case the analysed string does not determine the experiment result, a first match from the above list should be outputted.

## Sample Input

## Sample Output

- +
- \_
- ?
- ?
- \*
